

# Process Management in Linux

## ✧ What is a Process?

In Linux, a process is just a program that's running on your computer.

## Process States:

1. **Running(R)**: The process is actively using the CPU.
2. **Sleeping(S)**: The process is waiting for something, like input from the user or a response from the disk.
3. **Stopped(T)**: The process is paused. You can pause a process using Ctrl+Z.
4. **Zombie(Z)**: The process has finished, but it's still in the system because its parent process hasn't checked its results yet.

## Creating Processes:

- ◆ In Linux, processes are created using a system call called `fork()`. When a process calls `fork()`, it creates a copy of itself called the child process.
- ◆ If the child process needs to run a different program, it uses the `exec()` command to replace its program with the new one.

## Commands in Linux to manage processes:

**ps:** Shows a list of processes running on the system.

**ps aux:** shows all the processes with detailed information.

**top:** Shows live information about processes, like how much CPU and memory they are using.

**kill:** Stops a process. For example, `kill 1234` stops the process with PID 1234.

**nice:** Changes a process's priority. If a process has a lower priority, it gets less CPU time. For example, `nice -n 10 my_program` runs a program with lower priority.

**renice:** The "renice" command in Linux is used to change the priority of a currently running process.

**Jobs:** The jobs command is a command-line utility that provides a snapshot of the background processes associated with current shell sessions.

**fg and bg:** These are used to manage processes in the foreground or background. If you start a long-running task and want to

free up the terminal, you can use `bg` to run it in the background.

## Signals:

A signal is a message sent to a process, asking it to do something. Some common signals are:

**SIGINT:** Interrupts a process (usually `Ctrl+C` in the terminal).

**SIGTERM:** Asks a process to stop politely.

**SIGKILL:** Forcefully stops a process immediately (this can't be ignored).

## Scheduling and Priorities:

- ◆ Linux uses a scheduler to decide which process gets to use the CPU and for how long. Processes are given priority based on their nice value:
- ◆ The nice value ranges from -20 (high priority) to 19 (low priority).
- ◆ A process with a low nice value gets more CPU time than one with a high nice value.

## Note:

- ◆ When a process is done, the system clears it from memory and reclaims the resources it was using (like CPU time and memory).
- ◆ If a process finishes normally, the system removes it.
- ◆ If a process is killed, the system also removes it.
- ◆ If a child process finishes, the parent process has to check the child's exit status. If not, the child becomes a zombie.

Thank You !
